The Problem

Why did we build InfoCenter?

Information is scattered

Students and newcomers may need to check several social-media pages to find announcements.

Important updates get missed

When information is spread across different places, users can overlook announcements.

Too much irrelevant content

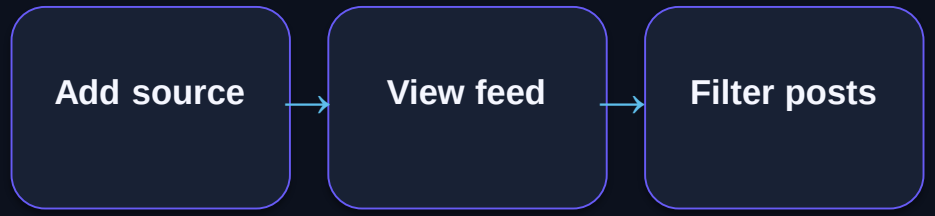

Finding one useful post among many updates can take time.

Our goal: help users find updates from selected sources in one place.

Our Solution: InfoCenter

One place to view updates from selected social-media sources

- Users add supported source links (Facebook, Instagram, or TikTok).
- InfoCenter brings available posts into one combined feed.
- Users can organize and find posts with tabs, tags, and keyword filters.
- Users can open the original post when they need more information.

Then open the original post if needed.

Functional Requirements

The four main functions described in our SRS

FR-1 Add & subscribe to sources

Paste a supported source link to add it to the user's update list.

FR-2 View aggregated feed

See updates from selected sources in one feed.

FR-3 Categorize and filter by tags

Create labels and show posts from selected tagged sources.

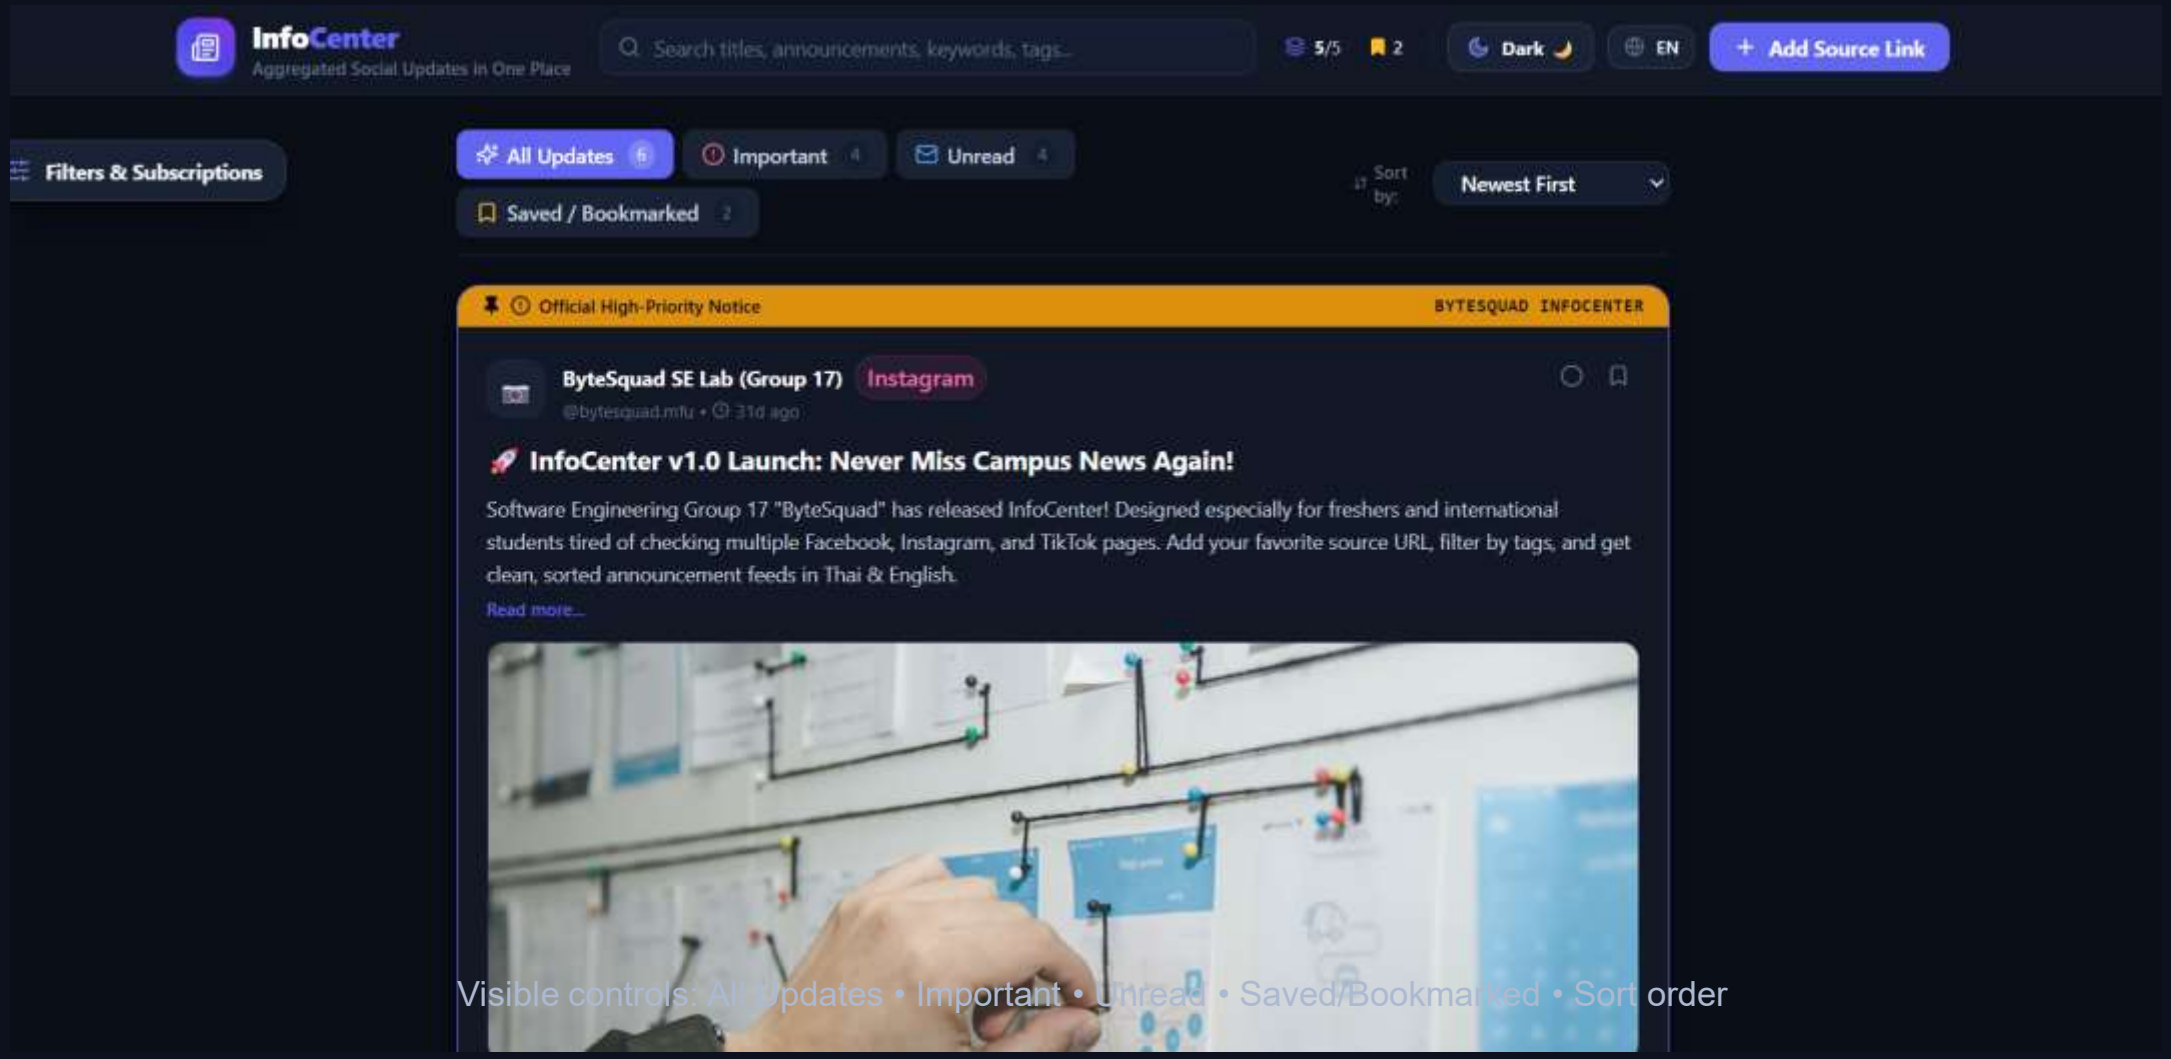

FR-4 Information sorting

Include or exclude posts using keywords.

These are the FRs listed in the team's SRS; confirm which ones are marked Must in the final project materials.

Prototype: Combined Feed

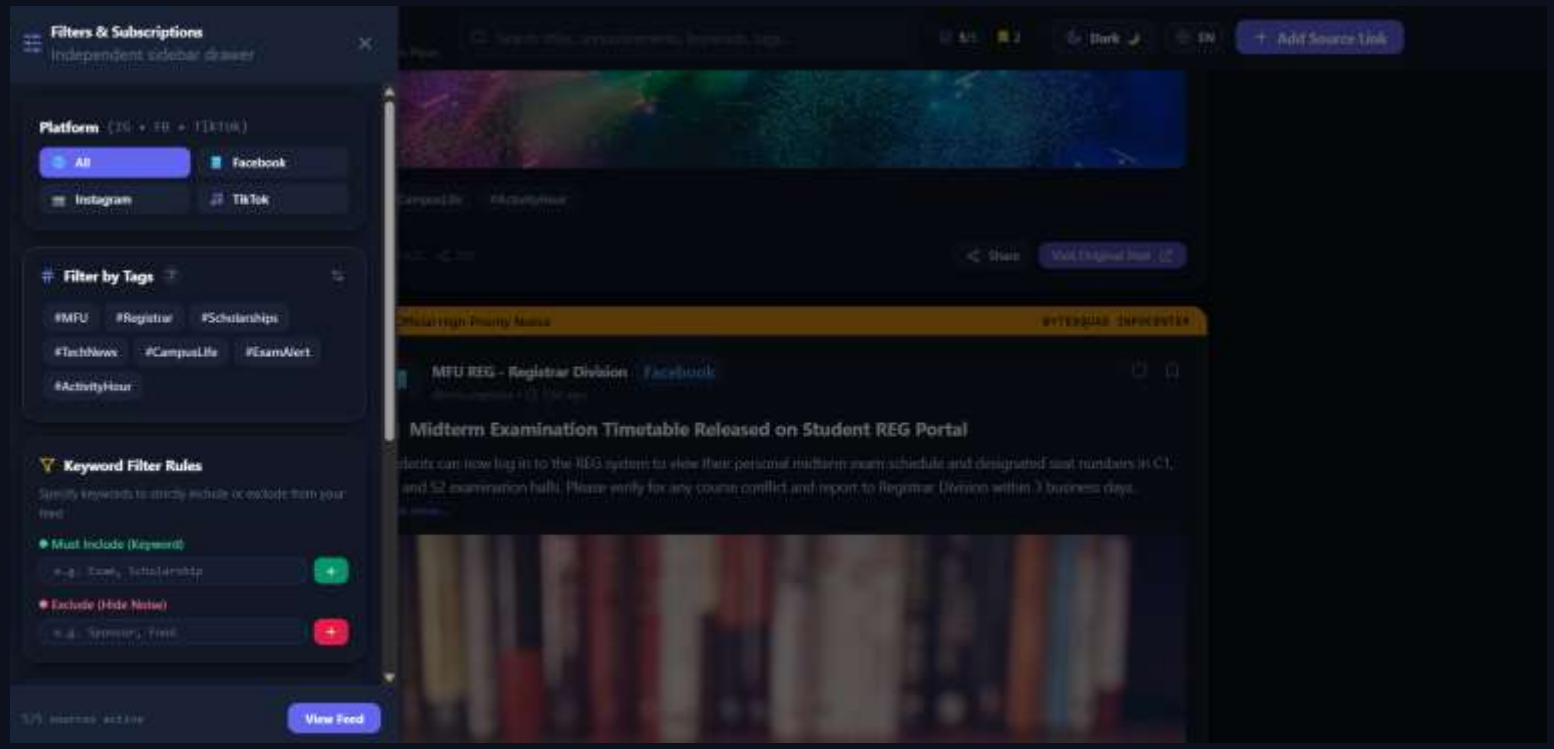

The main screen brings posts and feed controls together

Visible controls: All Updates • Important • Unread • Saved/Bookmarked • Sort order

Prototype: Filters & Subscriptions

Users can narrow the feed to the sources and topics they want

- Choose a platform: All, Facebook, Instagram, or TikTok.
- Filter by tags such as #MFU or #TechNews.
- Include keywords to find relevant posts.
- Exclude keywords to hide unwanted posts.

Technology & Project Structure

Technology information from the project documentation

Frontend

React 18 • TypeScript • Vite 5 • Tailwind CSS 3 • lucide-react

Backend

The repository includes a C# backend project for reading and processing Apify dataset data.

API integration

The frontend uses a REST API client for /api endpoints and includes mock-data fallbacks.

Development approach

Reuse-Oriented Development: reuse and integrate existing components, libraries, APIs, and AI services where appropriate.

Scope & Current Limitations

- Supported source types in the prototype: Facebook, Instagram, and TikTok.
- The app links users back to the original post; it does not replace the social platforms.
- Some interface content may use sample (mock) data when a working backend is unavailable.
- Automatic updates depend on backend operation and platform/API data access.
- Notifications while the app is closed and built-in commenting are outside the project scope.

Live Demo Flow

Suggested order for showing the prototype

1. **Show the combined feed** — Point out posts from different sources.
2. **Switch feed tabs** — Show All Updates, Important, Unread, and Saved/Bookmarked.
3. **Open Filters & Subscriptions** — Show platform choices and tags.
4. **Try keyword filters** — Demonstrate include and exclude keyword controls.
5. **Open an original post** — Show how users can continue to the source.

Thank You
